**GENEWEAVER™ I**

Yeast ORF cloning based on homologous recombination. This is the first in a series of vector cloning kits designed to accelerate the discovery of yeast gene function. With GENEWEAVER™I, any ORF can be cloned into *S. cerevisiae* for further study and manipulation.

**GENEPAIRS™ for Yeast:** These primer pairs have been tested and proven to amplify 99% of the calculated Open Reading Frames (ORFs) in the Saccharomyces Genome Database (http://genome-www.stanford.edu/Saccharomyces). The primers may be purchased as a set or individually. A common sequence has been added to the 5’ end of each forward, and similarly, to each reverse primer to allow cloning by homologous recombination and easy re-amplification.

**Yeast ORFs:** The yeast GENEPAIRS™ were used to individually amplify each Open Reading Frame in the Saccharomyces Genome Database (http://genome-www.stanford.edu/Saccharomyces). Because an amplified ORF has a common sequence at the 5’ and 3’ ends, a single pair of primers may be used to re-amplify any or all of the ORFs. These re-amplified ORFs are especially useful for making DNA arrays for gene expression studies.

**Yeast Genetic Footprinting Primers:** Genetic footprinting as described by V. Smith, et al. (1996 *Science* Dec. 20;274 (5295):2069) is a whole genome approach for quantitating how much each gene contributes to survival under a specific set of growth conditions. This ground breaking procedure has been used to discover genes essential to survival in the presence of various drugs, and also a gene whose absence actually enhances growth in high-salt media.

**GENEFILTERS™:** All of the yeast ORFs are individually spotted on a high-density membrane. The membrane is suitable for a number of whole genome studies involving hybridization with mRNA and cDNAs. This new product provides every lab with the ability to study differential gene expression using commercially available phosphorimaging devices and/or standard autoradiography.
